Response letter

Victor, Lizzie

August 2024

Outline

In their letter, Bogdziewicz et al. say that the reproduction synchrony among individuals has to be controlled by the solstice. It is explicitly one of the hypotheses our paper considers, and we do not believe our results invalidate it. We're sorry if something in our paper may have led them to believe the opposite, or to think that we addressed the risk of "*late frost damage*". Yet, we trully appreciate their interest in our work, and we are glad that it may stimulate fruitfull scientific discussion. Our results do show solstice is optimal, but also highlight some amount of variation across space.

The notion of "*temperature sensing window*" (in fact, some amount on correlation with a rolling window, Journe et al.) appears higher around the solstice (and may even start earlier, as shown in Fig1 in Bogdziewicz). Interestingly, the timing of this correlation between temperature and seed production also appear to vary across space (Journe et al., Fig. 1 in Bogdziewicz). However, the lack of quantification of this spatial variation—alongside an omission of possible temporal variation—make it difficult to compare their findings across latitude and with our results. Clearly, variation exists and will happen, but the extent to of variation that could possibly invalidate the "*celestial starting gun*" hypothesis remains unclear. Similarly, we believe that the lack of a true quantification of the scale under which the "*remarkable spatial synchrony*" is happening is an important missing piece of this hypothesis.
